Hybrid training under residual misspecification

Results by dataset × misspec family × γ × method

Exact-greedy CTR (%), paired contrasts, and DiD with 95% t CIs

OPC project

November 11, 2026

Abstract

This note explains the experiment from first principles and then reports **every locked cell with numbers**: absolute CTR levels, method contrasts (hybrid / OPC vs NLL), and difference-in-differences (DiD) with 95% confidence intervals. Tables are stratified by **dataset**, **misspec family**, γ, and **method**. The full hybrid grid (`nlres_grid_*`, n=40, methods including $f \in \{0.25, 0.5, 0.75\}$ and adapt) is still running for non-ML catalogs; ML SoftAND / SoftThresh / $R^\star$ grids and earlier multi-dataset $R^\star$ locks are included.

8 Reproducibility **81**

1 Problem setup (for a reader not in the loop)

1.1 Offline policy learning with logged bandit feedback

We have users x, items / actions $a \in \mathcal{A}$, and binary rewards $r \in \{0, 1\}$ (click). A logging policy π_0 collected a dataset $\mathcal{D} = \{(x_i, a_i, r_i, p_i)\}$ with propensities $p_i = \pi_0(a_i \mid x_i)$. A learner outputs a new policy π_θ. We evaluate with the **exact-greedy CTR** of π_θ in a simulated world whose click probabilities $q(x, a) = \Pr(r{=}1 \mid x, a)$ are known to the evaluator (but not used as training labels for the policy, except through the usual reward model / IPS machinery of each method).

Reported metric (percentage points of CTR):

$$V(\pi) = 100 \cdot \mathbb{E}_{x\sim\nu}\Big[q\big(x, \arg\max_a \pi(a \mid x)\big)\Big]. \tag{1}$$

1.2 Ground-truth world and the misspecification dial γ

The environment logit is an affine-bilinear "clean" score plus a residual:

$$\ell_\gamma(x, a) = \underbrace{b + u_x^\top v_a}_{\text{GT bilinear}} + \gamma \cdot \alpha \cdot \phi(x, a), \qquad \mathrm{sd}(\phi) = 1, \tag{2}$$

and $q = \sigma(\ell_\gamma)$ after a global offset that freezes a target reference CTR (here 5% under the logger). The scalar $\gamma \geq 0$ is the **dial**: $\gamma = 0$ is well-specified bilinear truth; large γ makes the residual ϕ dominate ranking.

Three residual families ϕ are used (unit-SD by construction after normalization):

- $R^\star$ (even map on a second random projection; $s{=}1, m{=}4, \psi{=}\tanh$). Empirically $\mathrm{sd}(\gamma\alpha\phi)/\mathrm{sd}(\mathrm{GT}) \approx 2.4\gamma$ (overshoots the nominal dial).
- **SoftAND*** (multiplicative gate; tracks sd_ratio $\approx \gamma$).
- **SoftThresh**τ=1.5 (thresholded residual; also tracks sd_ratio $\approx \gamma$).

A useful summary of "how loud is ϕ" is the logit variance share $\mathrm{Var}(\gamma\alpha\phi)/\mathrm{Var}(\ell_\gamma)$. SoftAND / SoftThresh at γ=0.5 keep $\approx 20\%$ variance on ϕ; $R^\star$ at the same nominal γ is louder ($\approx 59\%$).

1.3 Learners

All primary learners are matched linear policies with Optuna-tuned LR / epochs ($n_{\text{train}}{=}10^5$, $n_{\text{val}}{=}2{\cdot}10^4$, 20 trials, bias cell `high`). Methods in the tables:

- **NLL**: maximum likelihood on logged clicks (no IPS correction).
- **OPC/DR**: doubly robust offline policy learning (direct method + IPS).
- **hybrid_seq_**f: train with NLL for the first fraction f of the (selected) epoch budget, then switch to DR for the remainder. Locked default $f^\star{=}0.5$; the full grid also reports $f \in \{0.25, 0.75\}$.
- **hybrid_seq_adapt**: start with NLL, switch to DR when validation NLL plateaus (patience 2), with switch fraction clipped to $[0.25, 0.75]$.

1.4 Estimands: levels, contrasts, DiD

For a fixed dataset, misspec family, and γ, write $V_m(\gamma)$ for method m. Paired over seeds $s = 1, \ldots, n$:

$$\Delta_{m,m'}(\gamma) = V_m(\gamma) - V_{m'}(\gamma), \tag{3}$$

$$\mathrm{DiD}_{m,m'}(\gamma_1; \gamma_0) = \Delta_{m,m'}(\gamma_1) - \Delta_{m,m'}(\gamma_0). \tag{4}$$

Primary contrast vs likelihood: $\Delta_{\mathrm{H,NLL}}$ with H = `hybrid_seq_f0.5`. DiD asks: *does the hybrid advantage over NLL grow when we turn up misspecification?* CIs are seed-level Student-t: $\bar{x} \pm t_{0.975,n-1}\,\mathrm{SE}$, with $\mathrm{SE} = s/\sqrt{n}$.

1.5 Decision regret (no γ oracle)

Across locked cells, cell regret of a rule that picks hybrid or NLL is the forgone $|\Delta_{\mathrm{H,NLL}}|$ when the pick disagrees with the sign of the estimated mean. Empirically, **always-hybrid** has far smaller summed regret than always-NLL when γ is unknown.

2 Status snapshot

- **ML full hybrid grid** (`nlres_grid_ml_*`): SoftAND complete across γ; SoftThresh / $R^\star$ largely complete or near-complete (n up to 40; some mid-cells still filling $f \in \{0.25, 0.75, \text{adapt}\}$).
- **Anime** grid: in flight (partial seeds).
- **Myket / KuaiRand / KuaiRec** full hybrid grids: queued; earlier Phase-1 $R^\star$ locks (n=20) are included below.
- SoftAND n=40 catchup on ML (seeds 320–339) is complete for prior tags.

3 Full-grid study matrix (complete picture)

Planned confirmatory grid: **192** cells (dataset×misspec×γ), each with methods OPC/DR, NLL, hybrid $f \in \{0.25, 0.5, 0.75\}$, adapt; target n=40 seeds. Status now: **18** complete, **23** partial, **151** did not run. Partial cells still contribute seed-level estimates below (with current n and CIs). Did-not-run cells appear explicitly as "did not run".

4 When to use hybrid (aggregate)

Prefer hybrid_seq_f0.5 as the default vs pure likelihood when residual misspecification strength is unknown. Across dataset×misspec cells, summed regret of always-NLL is much larger than always-hybrid: well-spec (γ=0) costs are typically ≤0.5–0.8pt, while mid/extreme ϕ misspec yields +0.5 to +6pt H–NLL with CI LB¿0 on most R* and extreme SoftAND/SoftThresh cells. Use pure NLL only when you have a strong prior of bilinear well-specification and need to squeeze the last γ=0 points (e.g. kuairand full-catalog γ=0). OPC–NLL≥0.5 is a conservative 'misspec is loud' flag but is not a good gate for switching away from hybrid—it misses many mid-γ hybrid wins where OPC still trails NLL.

Best regret rule. `hybrid_unless_OPC_NLL_le_-1.0`. Summed regret (pt): always-NLL 74.65, always-hybrid 3.52, rule 2.95. Sign agreement with H−NLL: 41; clear wins caught: 26/28.

5 Dial calibration (MovieLens reward ratios)

Uniform (x, a) pairs; designed sd(ϕ) = 1 so SoftAND/SoftThresh track sd_ratio ≈ γ. $R^\star$ overshoots (≈ 2.4×).

7 Results by setup

Each subsection is one (**dataset**, **misspec**) pair. Absolute levels list *every* planned $\gamma\times$method for the full grid (complete / partial / did not run). Contrasts and DiD show numbers when estimable; otherwise an explicit missing-row.

7.1 anime / R*

Full-grid cells for this setup: 10 (complete 0, partial 10, did not run 0). Target $n = 40$. Planned $\gamma \in \{0, 0.25, 0.5, 0.6, 0.75, 1, 2, 4, 10, 100\}$.

DiD vs γ=0 (CTR points) with 95% CI

Definition: DiD = $\Delta(\gamma_1) - \Delta(\gamma_0)$ for the named contrast, paired over seeds present at both γ. Rows with status "did not run" or "partial pair" mean the γ=0 / γ_1 seed intersection was empty or incomplete.

DiD vs γ=0 (CTR points) with 95% CI

Definition: DiD = $\Delta(\gamma_1) - \Delta(\gamma_0)$ for the named contrast, paired over seeds present at both γ. Rows with status "did not run" or "partial pair" mean the γ=0 / γ_1 seed intersection was empty or incomplete.

DiD vs γ=0 (CTR points) with 95% CI

Definition: DiD = $\Delta(\gamma_1) - \Delta(\gamma_0)$ for the named contrast, paired over seeds present at both γ. Rows with status "did not run" or "partial pair" mean the γ=0 / γ_1 seed intersection was empty or incomplete.

DiD vs γ=0 (CTR points) with 95% CI

Definition: DiD = $\Delta(\gamma_1) - \Delta(\gamma_0)$ for the named contrast, paired over seeds present at both γ. Rows with status "did not run" or "partial pair" mean the γ=0 / γ_1 seed intersection was empty or incomplete.

DiD vs γ=0 (CTR points) with 95% CI

Definition: DiD = $\Delta(\gamma_1) - \Delta(\gamma_0)$ for the named contrast, paired over seeds present at both γ. Rows with status "did not run" or "partial pair" mean the γ=0 / γ_1 seed intersection was empty or incomplete.

DiD vs γ=0 (CTR points) with 95% CI

Definition: DiD = $\Delta(\gamma_1) - \Delta(\gamma_0)$ for the named contrast, paired over seeds present at both γ. Rows with status "did not run" or "partial pair" mean the γ=0 / γ_1 seed intersection was empty or incomplete.

DiD vs γ=0 (CTR points) with 95% CI

Definition: DiD = $\Delta(\gamma_1) - \Delta(\gamma_0)$ for the named contrast, paired over seeds present at both γ. Rows with status "did not run" or "partial pair" mean the γ=0 / γ_1 seed intersection was empty or incomplete.

DiD vs γ=0 (CTR points) with 95% CI

Definition: DiD = $\Delta(\gamma_1) - \Delta(\gamma_0)$ for the named contrast, paired over seeds present at both γ. Rows with status "did not run" or "partial pair" mean the γ=0 / γ_1 seed intersection was empty or incomplete.

DiD vs γ=0 (CTR points) with 95% CI

Definition: DiD = $\Delta(\gamma_1) - \Delta(\gamma_0)$ for the named contrast, paired over seeds present at both γ. Rows with status "did not run" or "partial pair" mean the γ=0 / γ_1 seed intersection was empty or incomplete.
